

# Pointers

- ❑ Pointers are variables that store the address of other variables.
- ❑ The pointer variable might be belonging to any of the data type such as int, float, char, double, short etc.
- ❑ Normal variable stores the value whereas pointer variable stores the address of the variable.
- ❑ If you have a variable **var** in your program, **&var** will give you its address in the memory.
- ❑ Pointer Syntax : data\_type \*var\_name; Example : int \*p; char \*p;
- ❑ Where, \* is used to denote that “p” is pointer variable and not a normal variable.

## C - Pointers

```
int var = 10;  
int *p;  
p = &var;
```

P is a pointer that stores the address of variable var.

The data type of pointer p and variable var should match because an integer pointer can only hold the address of integer variable.

205

a=5

604

P=205

```
Int a;  
Int *p;
```

```
P = &a;
```

209

b=8

205

a=5

604

P=209

```
Int a;  
Int *p;  
Int b;  
P=&b;
```

# Assigning addresses to Pointers

- `Int a=5;`
- `Int *p;`
- we give the address to pointer as `p=&a;`  
Here, 5 is assigned to the a variable. And, the address of a is assigned to the p pointer.
- If we want to print p  
`cout<<p; //205`  
`cout<<&a; //205`  
`cout<<&p; //604`  
`cout<<*p; //5 Dereferencing`

205

a=5

604

P=205

# Assigning addresses to Pointers

- `Int a=5;`
- `Int *p;`
- we give the address to pointer as `p=&a;`  
Here, 5 is assigned to the a variable. And, the address of a is assigned to the p pointer.
- If we want to print p  
`cout<<p; //205`  
`cout<<&a; //205`  
`cout<<&p; //604`  
`cout<<*p; //5 Dereferencing`  
`*p=8`  
  
`cout<<*p; //8`

205

a=8

604

P=205

# Some Important points

- Always C pointer is initialized to null, i.e. `int *p = null`.
- The value of null pointer is 0.
- & symbol is used to get the address of the variable.
- \* symbol is used to get the value of the variable that the pointer is pointing to.
- If a pointer in C is assigned to NULL, it means it is pointing to nothing.
- Pointer addition, multiplication, division are not allowed. You have to deference it first then you can Add, divide and multiply etc.
  - `int *ip; /* pointer to an integer */`
  - `double *dp; /* pointer to a double */`
  - `float *fp; /* pointer to a float */`
  - `char *ch /* pointer to a character */`
- The actual data type of the value of all pointers, whether integer, float, character, or otherwise, is the same, a long hexadecimal number that represents a memory address. The only difference between pointers of different data types is the data type of the variable or constant that the pointer points to.

`int x;` 

`x = 4;` 

`int *p;`  

`p = &x;`  

# Representation of integer

Suppose we take an integer

`int a=1025;`

1025 is representing as 32 bits because integer is of 4 bytes and every bytes contains 8 bits. So 1025 is representing the following way.

<b>00000000</b>	<b>00000000</b>	<b>00000100</b>	<b>00000001</b>
204	203	202	201

# Void pointer

`Void *p0;`

`P0=p1;`

We can't dereference it like we do in printing , and we can't do this `p0+1`  
We will discuss about this later.

# Common mistakes

- ☐ `int c, *pc;`
- ☐ `Pc=&c;`
- ☐ `// pc is address but c is not`
- ☐ `pc = c; // Error`
  
- ☐ `// &c is address but *pc is not`
- ☐ `*pc = &c; // Error`
- ☐ 

---
- ☐ `// both &c and pc are addresses`
- ☐ `pc = &c;`
  
- ☐ `// both c and *pc values`
- ☐ `*pc = c;`

Do not confuse on it

```
int main()
{
    int c = 5;
    int *p =
    &c;
    cout<<*p;
    // 5
    return 0;
}
```

Why didn't we get an error when using  
`int *p = &c;?`

It's because

`int *p = &c;`  
is equivalent to

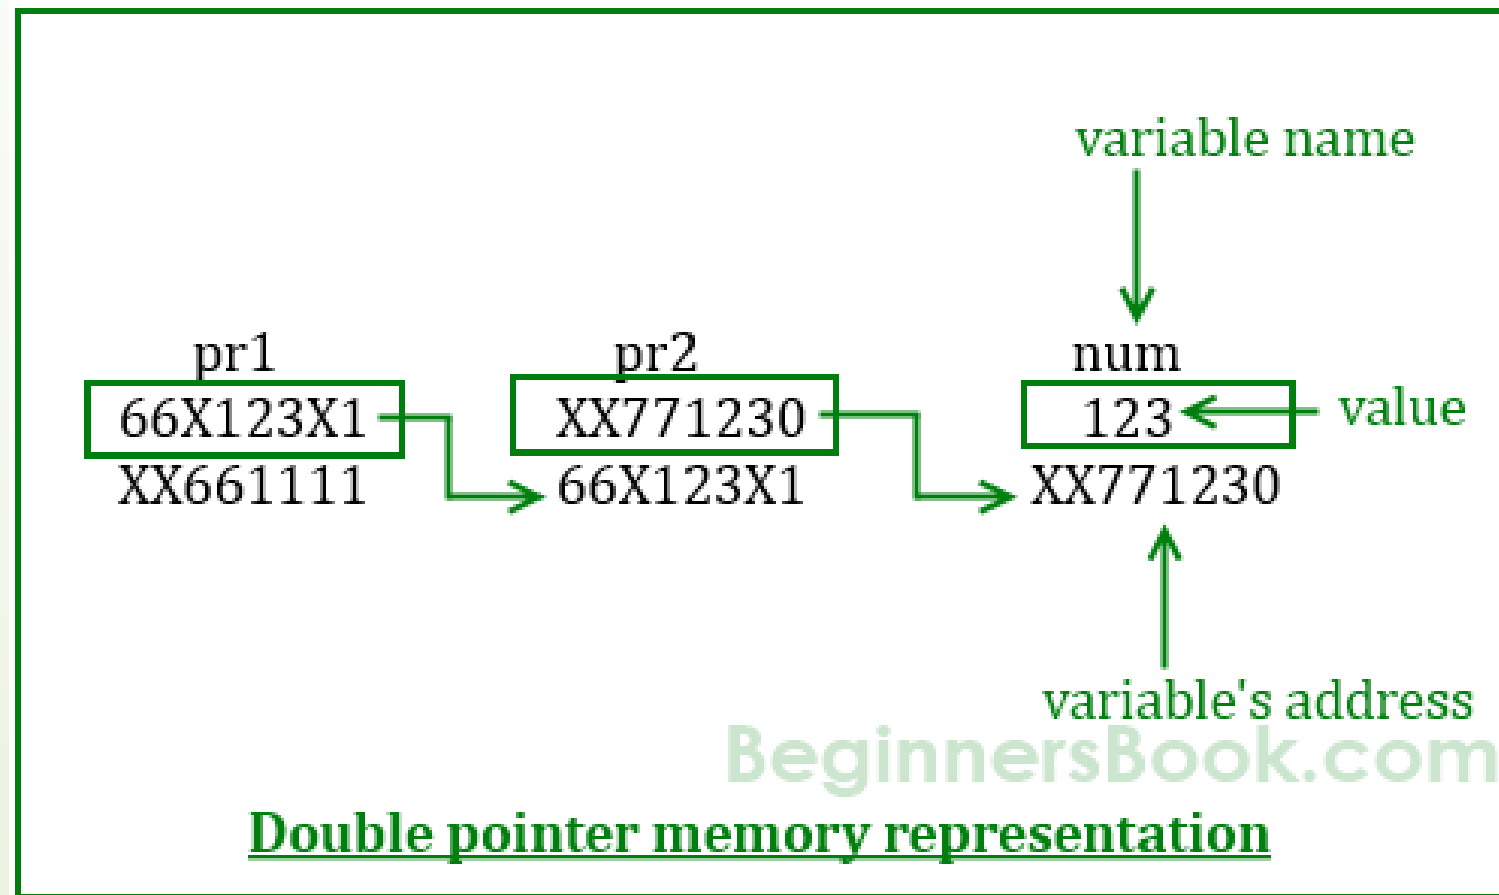

`int *p;`  
`p = &c;`

Find Sum  
Find MAX

# Pointers to Pointers

- When a pointer holds the address of another pointer then such type of pointer is known as **pointer-to-pointer** or **double pointer**.
- ```
int **pr1;  
pr1=&pr2;
```

# Pointers and arrays

- Suppose we declare an array arr,
- `int arr[5] = { 1, 2, 3, 4, 5 };`
- Assuming that the base address ( i.e address of the first element of the array ) of arr is 1000 and each integer requires two bytes, the five elements will be stored as follows:

The diagram shows a horizontal row of five adjacent rectangular boxes, each representing an element of the array. Below each box is its corresponding index and memory address.

|         |        |        |        |        |        |
|---------|--------|--------|--------|--------|--------|
| element | arr[0] | arr[1] | arr[2] | arr[3] | arr[4] |
| Address | 1000   | 1002   | 1004   | 1006   | 1008   |

- 
- Here variable arr will give the base address, which is a constant pointer pointing to the first element of the array, arr[0]. Hence arr contains the address of arr[0] i.e 1000. In short, arr has two purpose - it is the name of the array and it acts as a pointer pointing towards the first element in the array.
  - arr is equal to &arr[0] by default
  - We can also declare a pointer of type int to point to the array arr.

```
int *p;
```

```
p = arr;
```

```
// or,
```

```
p = &arr[0]; //both the statements are equivalent.
```

Similarly if you print \*(arr+1) it is same as arr[1]

Now we can access every element of the array arr using p++ to move from one element to another.

```
int main()
{
    int i;
    int a[5] = {1, 2, 3, 4, 5};
    int *p = a;    // same as int*p = &a[0]
    for (i = 0; i < 5; i++)
    {
        cout<<*p;
        p++;
    }

    return 0;
}
```

In the above program, the pointer \*p will print all the values stored in the array one by one. We can also use the Base address (a in above case) to act as a pointer and print all the values.

# Array to Function as parameters

- ❑ Arrays always passed as referenced parameter.
- ❑ It never get copied completely.
- ❑ We cant increment and decrement like pointer

# Why we use Pointers

- **Pointers** are used to store and manage the addresses of dynamically allocated blocks of memory. Such blocks are used to store data objects or arrays of objects.
- Most structured and object-oriented languages provide an area of memory, called the heap or free store, from which objects are dynamically allocated.
- you can even use **++** and **--** with a pointer, but not with an array name because this is a constant pointer and cannot be changed. So to summarise: An array's name is a **constant pointer** to the first element in the array that is **`a==&a[0]`** and **`*a==a[0]`**.

# Array to Function as parameters

```
#include<stdio.h>
int SumOfElements(int* A, int size)// "int* A" or "int A[]" ..it's the same..
{
    int i, sum = 0;

    for(i = 0;i< size;i++)
    {
        sum+= A[i]; // A[i] is *(A+i)
    }
    return sum;
}
int main()
{
    int A[] = {1,2,3,4,5};
    int size = sizeof(A)/sizeof(A[0]);
    int total = SumOfElements(A,size); // A can be used for &A[0]
    printf("Sum of elements = %d\n",total);
    printf("Main - Size of A = %d, size of A[0] = %d\n",sizeof(A),sizeof(A[0]));
}
```

```
int* fun()
{
    int A = 10;
    return (&A);
}

// Driver Code
int main()
{
    // Declare a pointer
    int* p;

    // Function call
    p = fun();

    cout<<p;
    cout<<*p;
    return 0;
}
```

ERRor

```
int* fun()
{
    // Declare a static integer
    static int A = 10;
    return (&A);
}

// Driver Code
int main()
{
    // Declare a pointer
    int* p;

    // Function call
    p = fun();

    // Print Address
    cout<<p;

    // Print value at the above address
    cout<<*p;
    return 0;
}
```

# Character Arrays and pointers

- Character arrays should be large enough to store a string.

|     |      |      |      |      |      |      |      |      |      |      |      |      |
|-----|------|------|------|------|------|------|------|------|------|------|------|------|
|     | 1000 | 1001 | 1002 | 1003 | 1004 | 1005 | 1006 | 1007 | 1008 | 1009 | 1010 | 1011 |
| arr | H    | e    | l    | l    | o    |      | w    | o    | r    | l    | d    | \0   |

12 bytes of memory is allocated to store 12 characters

---

# Functions in string.h

| String functions                   | Description                                                                                     |
|------------------------------------|-------------------------------------------------------------------------------------------------|
| <u><a href="#">strcat ( )</a></u>  | Concatenates str2 at the end of str1                                                            |
| <u><a href="#">strncat ( )</a></u> | Appends a portion of string to another                                                          |
| <u><a href="#">strcpy ( )</a></u>  | Copies str2 into str1                                                                           |
| <u><a href="#">strncpy ( )</a></u> | Copies given number of characters of one string to another                                      |
| <u><a href="#">strlen ( )</a></u>  | Gives the length of str1                                                                        |
| <u><a href="#">strcmp ( )</a></u>  | Returns 0 if str1 is same as str2. Returns <0 if str1 < str2. Returns >0 if str1 > str2         |
| <u><a href="#">strcmpi ( )</a></u> | Same as strcmp() function. But, this function negotiates case. "A" and "a" are treated as same. |
| <u><a href="#">strchr ( )</a></u>  | Returns pointer to first occurrence of char in str1                                             |
| <u><a href="#">strrchr ( )</a></u> | last occurrence of given character in a string is found                                         |

|                                    |                                                                  |
|------------------------------------|------------------------------------------------------------------|
| <u><a href="#">strstr ( )</a></u>  | Returns pointer to first occurrence of str2 in str1              |
| <u><a href="#">strrstr ( )</a></u> | Returns pointer to last occurrence of str2 in str1               |
| <u><a href="#">strdup ( )</a></u>  | Duplicates the string                                            |
| <u><a href="#">strlwr ( )</a></u>  | Converts string to lowercase                                     |
| <u><a href="#">strupr ( )</a></u>  | Converts string to uppercase                                     |
| <u><a href="#">strrev ( )</a></u>  | Reverses the given string                                        |
| <u><a href="#">strset ( )</a></u>  | Sets all character in a string to given character                |
| <u><a href="#">strnset ( )</a></u> | It sets the portion of characters in a string to given character |
| <u><a href="#">strtok ( )</a></u>  | Tokenizing given string using delimiter                          |

# Character Arrays and pointers

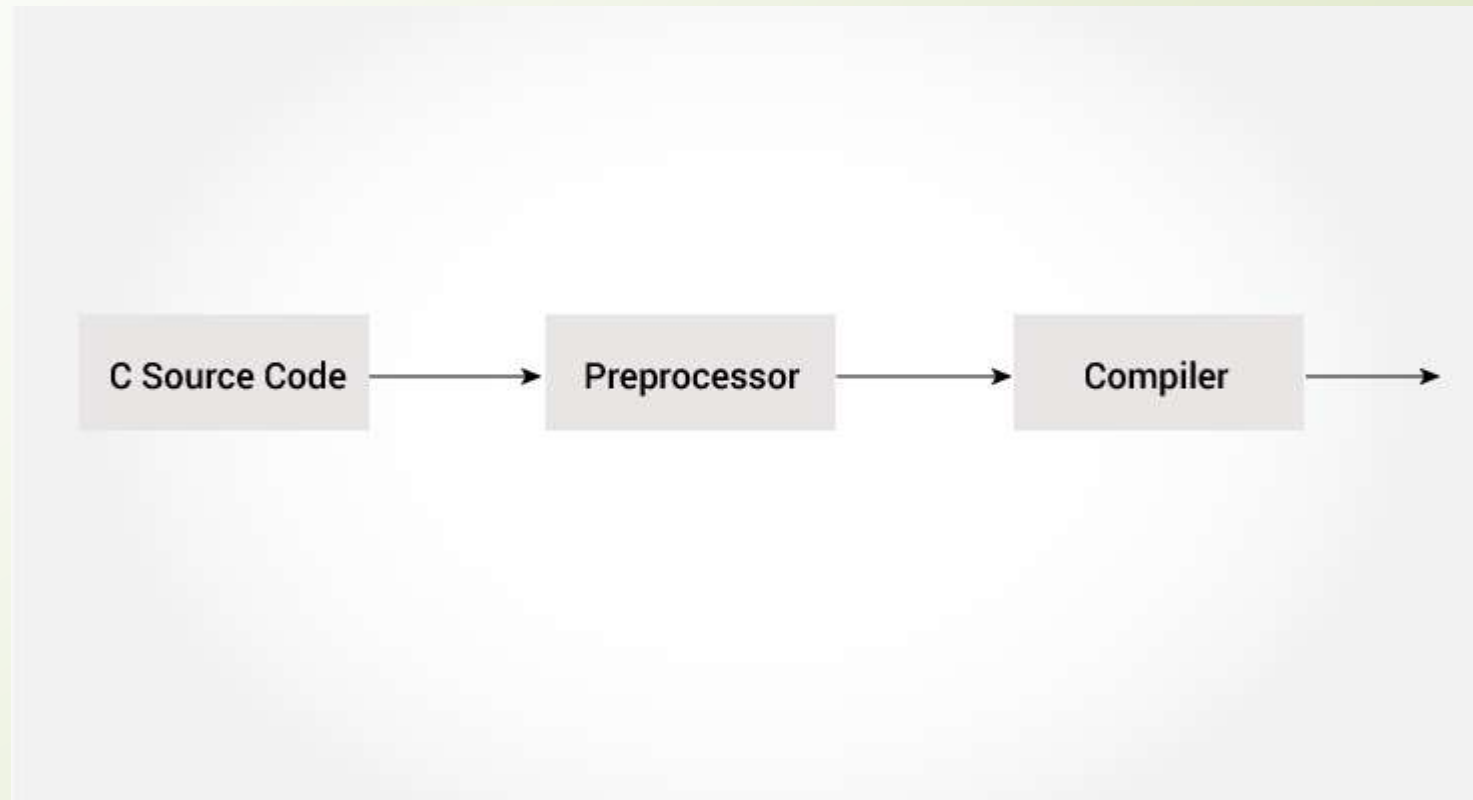

- Like we can handle pointers with array, similarly we can use character type pointers for character arrays.

```
char arr[] = "Hello"; // array version  
char *ptr ;// pointer version  
ptr=arr ;
```

- We can also print the array as ptr[2];
- Ptr[0] = A; //Aello
- \*ptr=A;
- Ptr++...

# Macros

- With **macro**(#define): **macro** will be replaced with its **value** in source code compile time only, so compiler does not need to look into memory even single time, **it** compiles code directly with **constant value**. So **it** is better to **use macro** than **constant** variable

# Dynamic Memory

- Sometimes the size of the array you declared may be insufficient. To solve this issue, you can allocate memory manually during run-time. This is known as dynamic memory allocation in C programming.
- 

# Heap

- Many times, you are not aware in advance how much memory you will need to store particular information in a defined variable and the size of required memory can be determined at run time.
- You can allocate memory at run time within the heap for the variable of a given type using a special operator in C++ which returns the address of the space allocated. This operator is called **new** operator.
- If you are not in need of dynamically allocated memory anymore, you can use **delete** operator, which de-allocates memory that was previously allocated by new operator.

# Heap

```
double* pvalue = NULL; // Pointer initialized with null
pvalue = new double;
double* pvalue = NULL;
if( !(pvalue = new double )) {
    cout << "Error: out of memory." <<endl;
    exit(1);
}
```

# Heap deletion

At any point, when you feel a variable that has been dynamically allocated is not anymore required, you can free up the memory that it occupies in the free store with the 'delete' operator as follows –

```
delete pvalue;
```

# Dynamic Memory Allocation for Arrays

```
char* pvalue = NULL;    // Pointer initialized with null  
pvalue = new char[20];  
delete [] pvalue;
```

```
double** pvalue = NULL; // Pointer initialized with null  
pvalue = new double [3][4];  
delete [] pvalue;
```

# Dynamic Memory Allocation for Arrays

UNION and INTERSECTION

# MEMORY LEAK & DANGLING POINTERS

A dangling pointer points to memory that has already been freed. The storage is no longer allocated. Trying to access it might cause a Segmentation fault.

```
int *c = new int();
```

```
Delete c;
```

```
*c = 3; //writing to freed location!
```

A memory leak is memory which hasn't been freed, there is no way to access (or free it) now, as there are no ways to get to it anymore. (E.g. a pointer which **was** the only reference to a memory location **dynamically allocated** (and not freed) which points somewhere else now.)

```
void func(){
```

```
    char *ch = new int(10);
```

```
}
```

```
//ch not valid outside, no way to access malloc-ed memory
```

# Character Arrays

```
#include <iostream>

const max_len = 256;

int main()
{
    using namespace std;

    cout << "Please enter string: ";

    char* str = new char[max_len +
1];

    for (int i = 0; i < max_len; i++)
    {
```

```
        cin >> str[i];
        if (str[i] == '\n')
        {
            str[i] = '\0';
            break;
        }
    }
    cout << "Entered string is:" << str << endl;
    delete [] str;

    return 0;
```

# Unusual behaviour with character pointers

```
using namespace std;

// Driver Code
int main()
{
    // Integer array
    int a[] = { 1, 2, 3 };

    // Character array
    char ch[] = "abc";

    // Print the value of a and b
    cout << a << endl;

    cout << ch << endl;
    return 0;
}
```

## Output:

```
0x7ffc623e56c0
abc
```

# Unusual behaviour with character pointers

```
#include <iostream>
using namespace std;

// Driver Code
int main()
{
    // Character array b
    char b[] = "abc";

    // Pointer to character array
    char* c = &b[0];

    // Print the value of c
    cout << c << endl;
}
```

**Output:**

abc

Explanation:

In this example as well, the character type pointer `c` is storing the base address of the char array `b[]` and hence when used with `cout`, it starts printing each and every character from that base address till it encounters a NULL character.

# Dynamic character array

```
#include <iostream>
#include <cstring>
using namespace std;
int main()
{
    char *s1=new char[50];
    char *s2=new char[50];

    cout << "Enter string s1: ";
    cin.getline(s1, 50);

    cout << "Enter string s2: ";
    cin.getline(s2, 50);

    strcat(s1, s2);

    cout << "s1 = " << s1 << endl;
    cout << "s2 = " << s2;

}
```

# Void Pointer

A void pointer is a pointer that has no associated data type with it. A void pointer can hold address of any type and can be typecasted to any type.

```
int a = 10;  
char b = 'x';  
  
void *p = &a; // void pointer holds address of  
int 'a'  
p = &b; // void pointer holds address of char 'b'
```

# Facts about Void Pointer

void pointers cannot be dereferenced. For example the following program doesn't compile.

```
#include<iostream>
using namespace std;
int main()
{
    int a = 10;
    void *ptr = &a;
    cout<< *ptr;
    return 0;
}
```

**The following program compiles and runs fine.**

```
#include<iostream>
using namespace std;
int main()
{
    int a = 10;
    void *ptr = &a;
    cout<< *(int *)ptr;
    return 0;
}
```

# Pointers to 2D array

- ❑ In a two dimensional array, we can access each element by using two subscripts, where first subscript represents the row number and second subscript represents the column number.
- ❑ The elements of 2-D array can be accessed with the help of pointer notation also. Suppose `arr` is a 2-D array, we can access any element `arr[i][j]` of the array using the pointer expression `*(*(arr + i) + j)`. Now we'll see how this expression can be derived.

# Pointers to 2D array

❑ `int arr[3][4] = { {1, 2, 3, 4}, {5, 6, 7, 8}, {9, 10, 11, 12} };`

|       | Col 1 | Col 2 | Col 3 | Col 4 |
|-------|-------|-------|-------|-------|
| Row 1 | 1     | 2     | 3     | 4     |
| Row 2 | 5     | 6     | 7     | 8     |
| Row 3 | 9     | 10    | 11    | 12    |

Since memory in a computer is organized linearly it is not possible to store the 2-D array in rows and columns. The concept of rows and columns is only theoretical, actually, a 2-D array is stored in row-major order i.e rows are placed next to each other. The following figure shows how the above 2-D array will be stored in memory.

| arr[0][0] |      |      |      | arr[1][0] |      |      |      | arr[2][0] |      |      |      |
|-----------|------|------|------|-----------|------|------|------|-----------|------|------|------|
| 5000      | 5004 | 5008 | 5012 | 5016      | 5020 | 5024 | 5028 | 5032      | 5036 | 5040 | 5044 |
| 1         | 2    | 3    | 4    | 5         | 6    | 7    | 8    | 9         | 10   | 11   | 12   |
| Row 1     |      |      |      | Row 2     |      |      |      | Row 3     |      |      |      |

# Pointers to 2D array

Each row can be considered as a 1-D array, so a two-dimensional array can be considered as a collection of one-dimensional arrays that are placed one after another.

So here *arr* is an array of 3 elements where each element is a 1-D array of 4 integers.

# Pointers to 2D array

Since *arr* is a 'pointer to an array of 4 integers', according to pointer arithmetic the expression *arr* + 1 will represent the address 5016 and expression *arr* + 2 will represent address 5032.

So we can say that *arr* points to the 0<sup>th</sup> 1-D array, *arr* + 1 points to the 1<sup>st</sup> 1-D array and *arr* + 2 points to the 2<sup>nd</sup> 1-D array.

|                |   |                                                |   |                                           |   |             |
|----------------|---|------------------------------------------------|---|-------------------------------------------|---|-------------|
| <b>arr</b>     | - | <b>Points to 0<sup>th</sup> element of arr</b> | - | <b>Points to 0<sup>th</sup> 1-D array</b> | - | <b>5000</b> |
| <b>arr + 1</b> | - | <b>Points to 1<sup>st</sup> element of arr</b> | - | <b>Points to 1<sup>st</sup> 1-D array</b> | - | <b>5016</b> |
| <b>arr + 2</b> | - | <b>Points to 2<sup>nd</sup> element of arr</b> | - | <b>Points to 2<sup>nd</sup> 1-D array</b> | - | <b>5032</b> |

|                          |                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------|
| <b>arr</b>               | <b>Points to 0<sup>th</sup> 1-D array</b>                                         |
| <b>*arr</b>              | <b>Points to 0<sup>th</sup> element of 0<sup>th</sup> 1-D array</b>               |
| <b>(arr + i)</b>         | <b>Points to i<sup>th</sup> 1-D array</b>                                         |
| <b>*(arr + i)</b>        | <b>Points to 0<sup>th</sup> element of i<sup>th</sup> 1-D array</b>               |
| <b>*(arr + i) + j)</b>   | <b>Points to j<sup>th</sup> element of i<sup>th</sup> 1-D array</b>               |
| <b>*(*(arr + i) + j)</b> | <b>Represents the value of j<sup>th</sup> element of i<sup>th</sup> 1-D array</b> |

- To access an individual element of our 2-D array, we should be able to access any jth element of ith 1-D array.
- Since the base type of \*(arr + i) is int and it contains the address of 0th element of ith 1-D array, we can get the addresses of subsequent elements in the ith 1-D array by adding integer values to \*(arr + i).
- For example \*(arr + i) + 1 will represent the address of 1<sup>st</sup> element of 1<sup>st</sup> element of ith 1-D array and \*(arr+i)+2 will represent the address of 2nd element of ith 1-D array.
- Similarly \*(arr + i) + j will represent the address of jth element of ith 1-D array. On dereferencing this expression we can get the jth element of the ith 1-D array.

- For example  $*(arr + i) + 1$  will represent the address of 1<sup>st</sup> element of 1<sup>st</sup> element of  $i$ th 1-D array and  $*(arr+i)+2$  will represent the address of 2nd element of  $i$ th 1-D array.
- Similarly  $*(arr + i) + j$  will represent the address of  $j$ th element of  $i$ th 1-D array. On dereferencing this expression we can get the  $j$ th element of the  $i$ th 1-D array.

```
int main()
{
    int arr[3][4] = {
        { 10, 11, 12, 13 },
        { 20, 21, 22, 23 },
        { 30, 31, 32, 33 }
    };

    int i, j;
    for (i = 0; i < 3; i++)
    {
        cout<< i, arr[i], *(arr + i);

        for (j = 0; j < 4; j++)
            cout<<arr[i][j]<< (*(arr + i) + j);
        cout<<"\n";
    }

    return 0;
}
```

//To delete the outer array

//which contained the pointers

//of all the inner arrays

return 0;

}

# Accessing ctype string via pointer

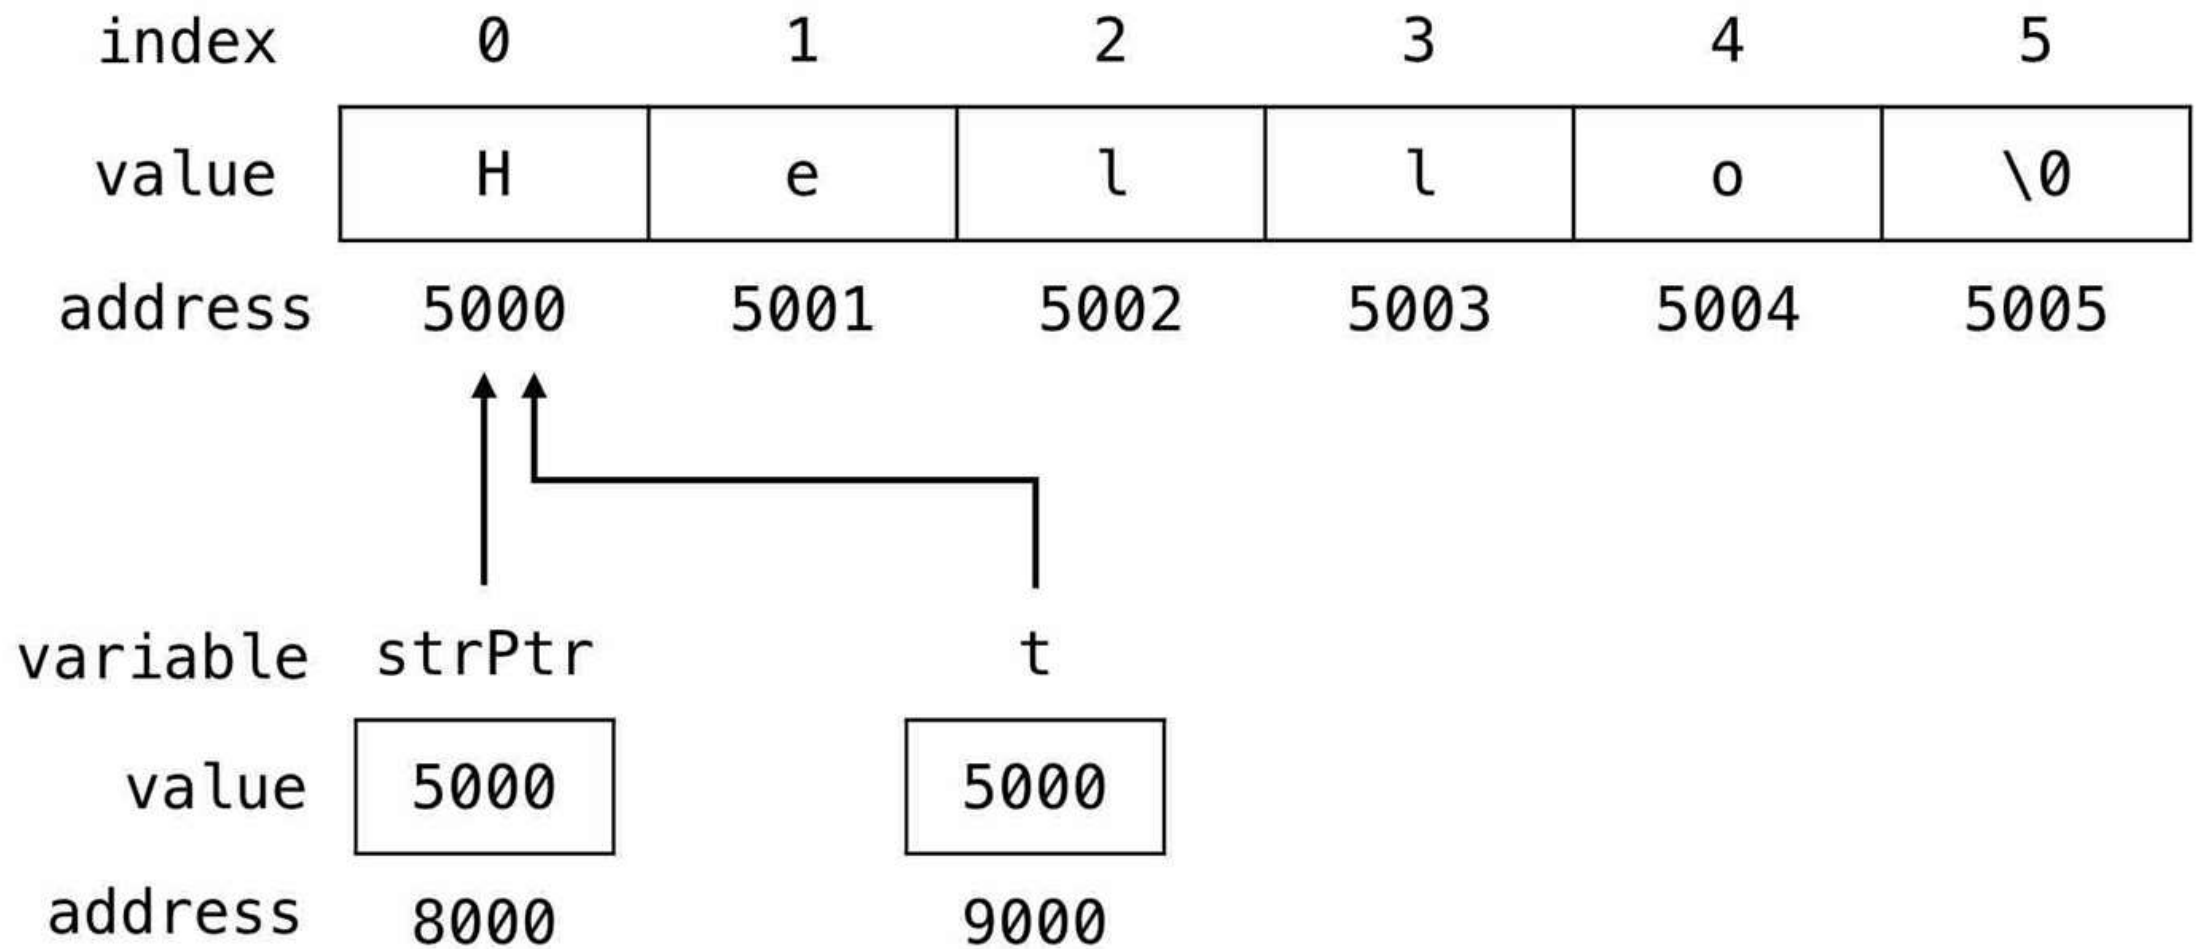

```
int main() {  
    // string variable  
    char str[6] = "Hello";  
  
    // pointer variable  
    char *ptr = str;  
  
    // print the string  
    while(*ptr != '\0') {  
        cout<< *ptr;  
  
        // move the ptr pointer to the next memory  
        location  
        ptr++;  
    }  
}
```

# Using pointer to store string

```
int main() {  
  
    // pointer variable to store string  
    char *strPtr = "Hello";  
  
    // temporary pointer variable  
    char *t = strPtr;  
  
    // print the string  
    while(*t != '\0') {  
        cout<< *t;  
  
        // move the t pointer to the next memory location  
        t++;  
    }  
}
```

```
char *strPtr = "Hello";
```

# Array of strings

```
int main() {  
  
    char city[4][12] = {  
        "Chennai",  
        "Kolkata",  
        "Mumbai",  
        "New Delhi"  
    };  
}
```

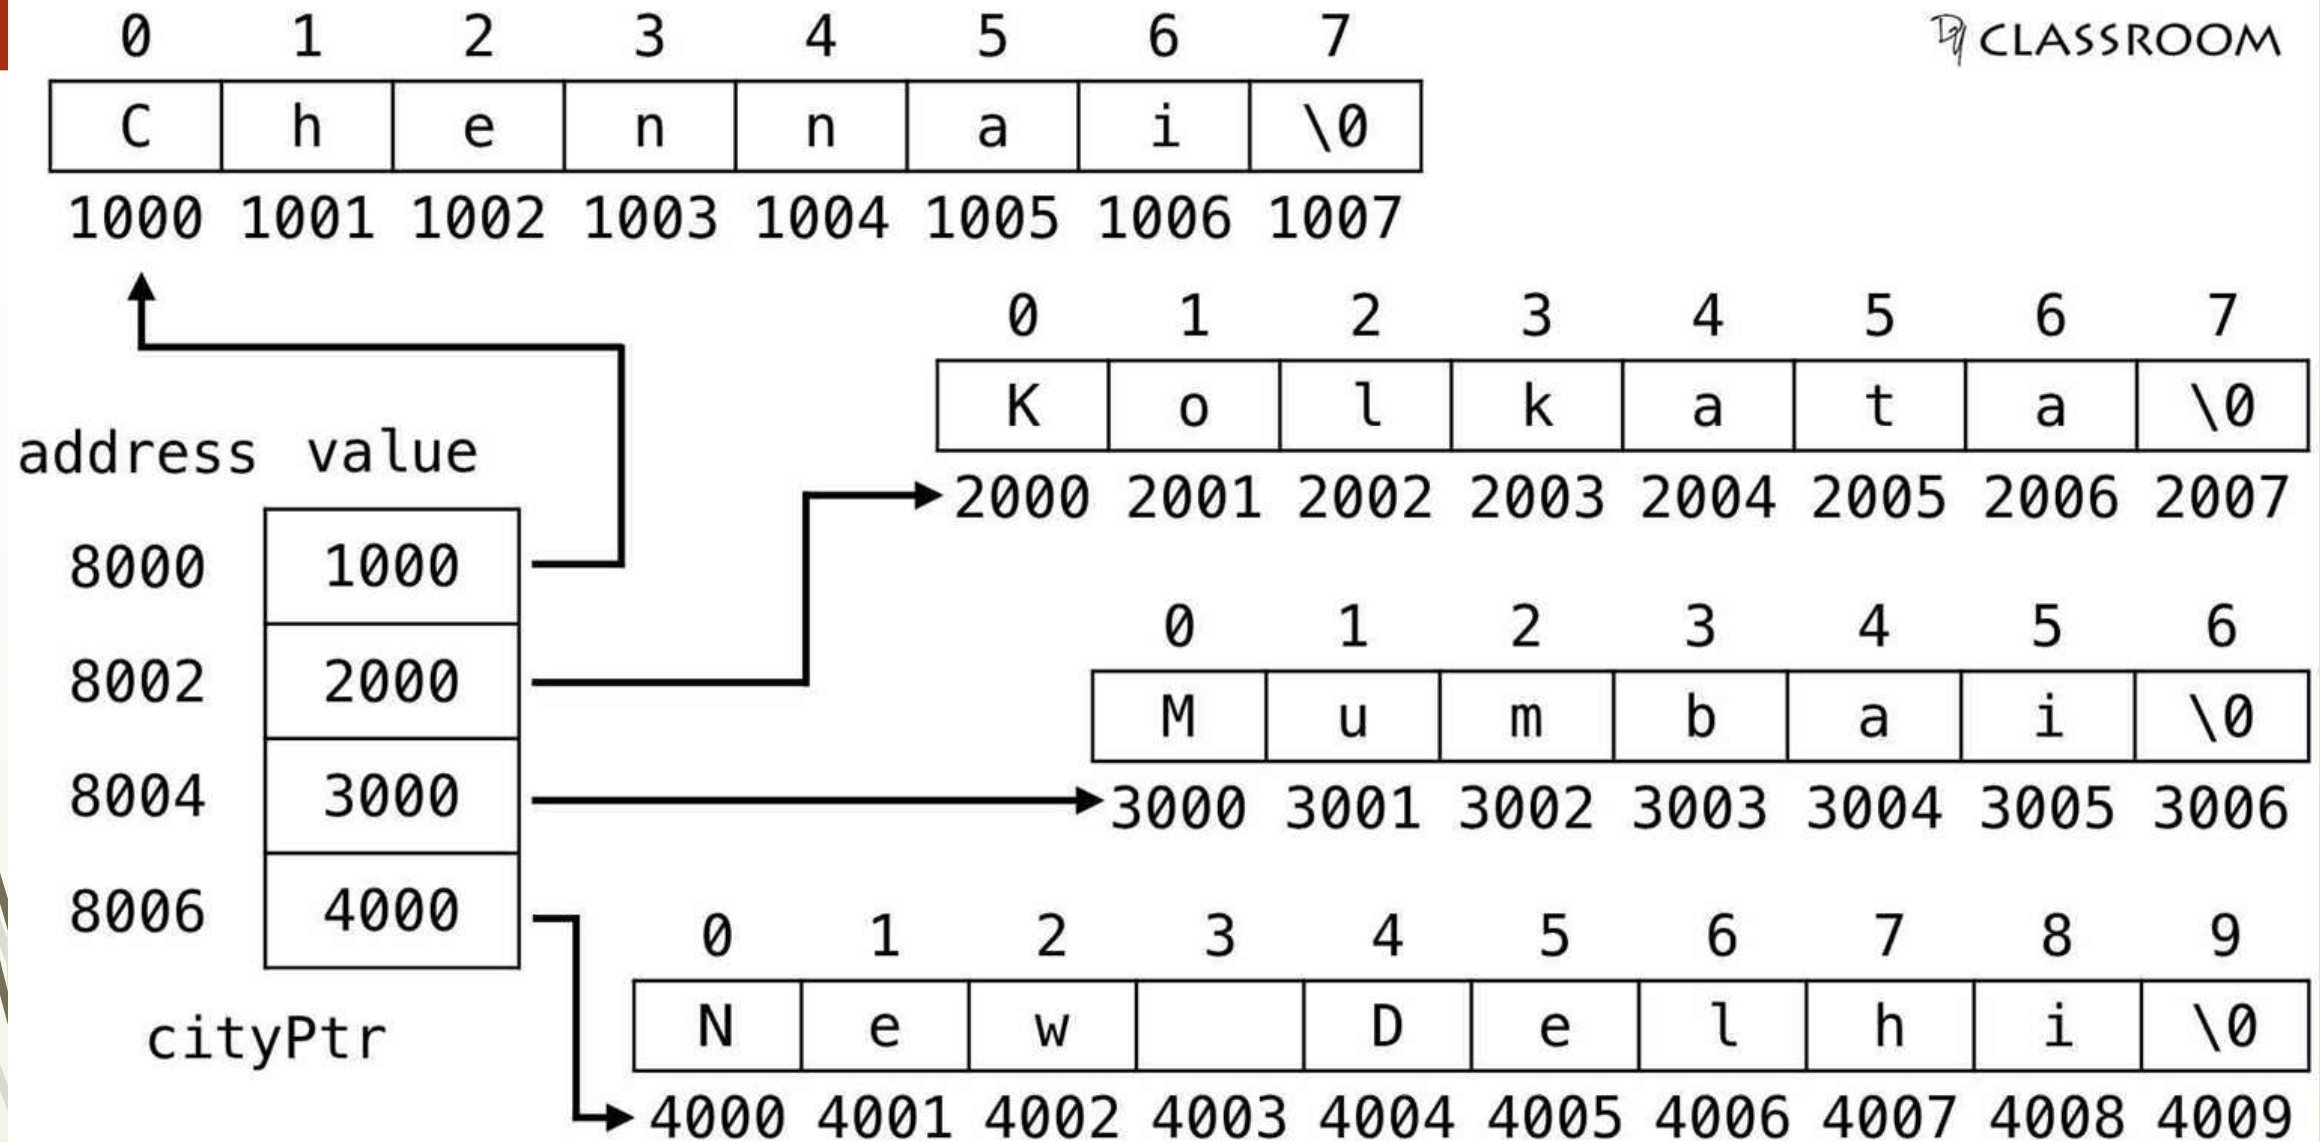

```
char city[4][12] = {  
    "Chennai",  
    "Kolkata",  
    "Mumbai",  
    "New Delhi"  
};
```

CLASSROOM

|   | 0 | 1 | 2 | 3 | 4 | 5 | 6  | 7  | 8 | 9  | 10 | 11 |
|---|---|---|---|---|---|---|----|----|---|----|----|----|
| 0 | C | h | e | n | n | a | i  | \0 |   |    |    |    |
| 1 | K | o | l | k | a | t | a  | \0 |   |    |    |    |
| 2 | M | u | m | b | a | i | \0 |    |   |    |    |    |
| 3 | N | e | w |   | D | e | l  | h  | i | \0 |    |    |

# character array

```
int main() {  
  
    char *cityPtr[4] = {  
        "Chennai",  
        "Kolkata",  
        "Mumbai",  
        "New Delhi"  
    };  
}
```

# string array

```
int main()
{
    const int MAX = 80; //max characters in string
    char str[MAX]; //string variable str
    Chapter 7
    290
    cout << "Enter a string: ";
    cin >> str; //put string in str
    //display string from str
    cout << "You entered: " << str << endl;
    return 0;
}
```

The definition of the string variable str looks like (and is) the definition of an array of type char:

```
char str[MAX];
```

# Arrays of Strings

```
#include <iostream>
using namespace std;
int main()
{
    const int DAYS = 7; //number of strings in array
    const int MAX = 10; //maximum size of each string
    //array of strings
    char star[DAYS][MAX] = { "Sunday", "Monday", "Tuesday",
                             "Wednesday", "Thursday",
                             "Friday", "Saturday" };
    for(int j=0; j<DAYS; j++) //display every string
        cout << star[j] << endl;
    return 0;
}
```
